Planteo del problema

En este trabajo práctico se utilizará un dataset que contiene 4000 títulos de una plataforma de streaming. El archivo credits train contiene los actores y directores para estas películas y series. El objetivo de trabajo es predecir la calificación de IMDB a partir de otras covariables para cada título. En este trabajo, se va a considerar la pérdida cuadrática como forma de evaluar modelos.

Análisis exploratorio de datos (EDA)

En esta sección vamos a realizar una exploración del dataset. (a) ¿Hay algún género que parezca estar más asociado con el puntaje del título? (b) ¿Cómo fue evolucionando este puntaje a lo largo del tiempo? (c) ¿Hay algún actor o director asociado con mayores o menores puntajes? (d) ¿Las películas más populares son las mejor puntuadas?

Antes de comenzar el análisis de EDA, tenemos que realizar una limpieza del dataset. Para esto eliminamos valores nulos, duplicados y dos columnas que presentaban un porcentaje muy alto de valores nulos. Asimismo, veremos que el dataset contiene información de películas y series, pero nos quedaremos solamente con los datos relacionados a las películas.

```

\caption{ Promedio de IMDB_SCORE en función de los países} \end{figure}

\caption{ Boxplot de IMDB_SCORE de actores/directores} \end{figure} ### Modelos lineales mixtos

Los modelos lineales mixtos fueron propuestos por (Laird and Ware 1982) y en ellos se asume que existe una relación entre el vector de observaciones Y_i del sujeto o grupo i y las covariables.

La forma general de un modelo lineal mixto es:

$$Y = Xb + Zu + e$$

donde: Y es el vector de respuesta (datos), X y Z son matrices de diseño conocidas, b es un vector de parámetros fijos, u (efectos aleatorios) y e (error) son vectores aleatorios no observables. Las esperanzas matemáticas de u y e , se asumen igual a cero.

- 2) A continuación vamos a implementar estos modelos en el marco del objetivo de este trabajo práctico: estimar el IMDB score de las películas.
- a) Plantear un modelo de efectos fijos para predecir el puntaje de IMDB únicamente en función del país de origen.

- Modelo lineal sin intercept con un efecto fijo por país

```

## refitting model(s) with ML (instead of REML)

## Data: title
## Models:
## fit_2: imdb_score ~ (1 | production_countries)
## fit_3: imdb_score ~ (release_year | production_countries)
##      npar    AIC    BIC logLik deviance Chisq Df Pr(>Chisq)
## fit_2     3 7186.9 7204.2 -3590.4   7180.9
## fit_3     5 7160.4 7189.3 -3575.2   7150.4 30.451  2 2.441e-07 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

De los resultados observamos que al incorporar en el modelo la variable release year el BIC disminuyo y además resultado estadísticamente significativo. Lo que implica que al incorporar dicha variable se reduzo la varianza del modelo.

- (b) Usando el modelo de efectos aleatorios del item anterior, decidir si agregaría la variable release year separando la data en dos: entrenamiento y testeo (estimar los coeficientes usando la data de entrenamiento y evaluarlo usando la de testeo).

A partir de ahora vamos a separar nuestro dataset en dos: uno de training o entrenamiento para ajustar el modelo y otro de testeo, para evaluar la performance del mismo.

```
##      modelo      RMSE
## 1 sin year 0.9799215
## 2 con year 0.9701066
```

- (c) Comparar ambos items anteriores.

Si bien en este caso se llega a la misma conclusión, siempre es conveniente evaluar los modelos utilizando un dataset independiente. De esta forma podremos analizar si el modelo puede generalizar correctamente y estimar la variable de interes usando muestras que no las ha analizado para estimar los parámetros de los modelos.

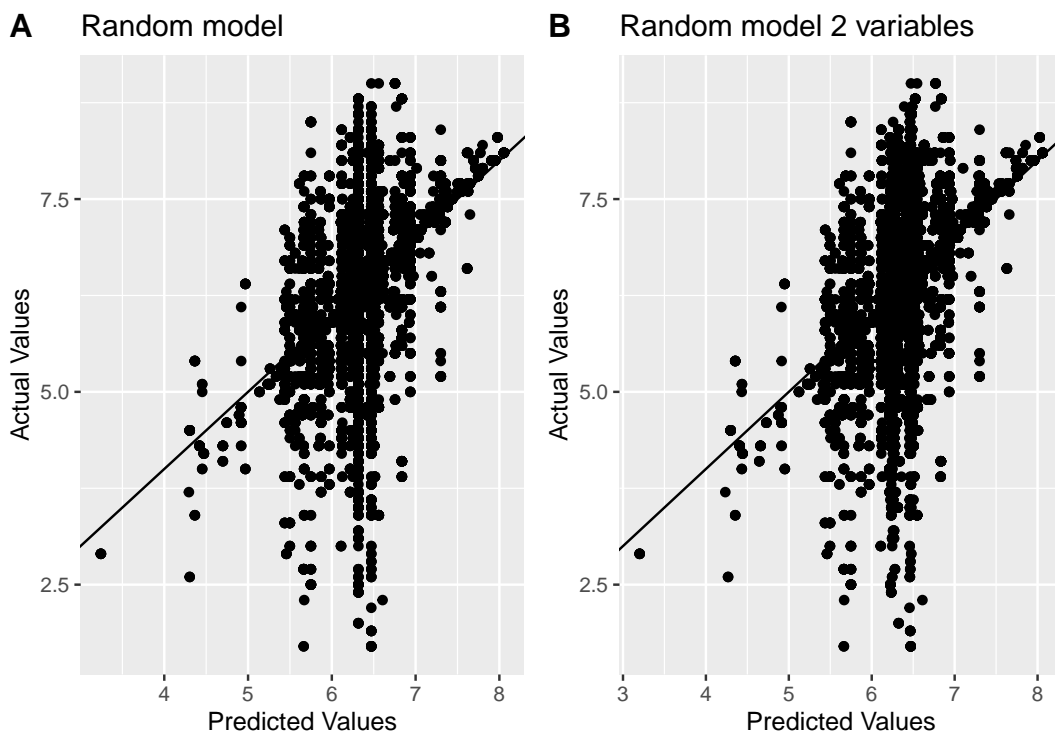

Figura 5: Comparación entre los valores observados y estimados de cada modelo

Modelos aditivos generalizados (GAM) Los GAMs (del inglés generalized additive models) son una generalización de los GLMs para incorporar formas no lineales de los predictores (plines, Polinomios, o funciones Step, etc...). El proceso de suavización en GAMs se lleva a cabo a través de los suavizadores (smoothers), entre los que destacan, entre otros, los Splines penalizados P-Splines.

Al igual que en la sección anterior, vamos a implementar estos modelos para estimar la variable `IMDB_score`.

- a) Usando únicamente la variable `release year`, predecir la popularidad de cada título (usando un tipo de modelo que crea adecuado) con una curva de splines penalizados. Usar $k = 1, 2, 3, 5, 10, 20, 50$ nodos y comparar todas las curvas estimadas en un mismo gráfico.

Para cumplir con esta consigna utilizamos ciclos `for` para fitear cada modelos usando distintos valores de nodos.

```
## Loading required package: nlme

##
## Attaching package: 'nlme'

## The following object is masked from 'package:lme4':
##
##     lmList

## The following object is masked from 'package:dplyr':
##
##     collapse

## This is mgcv 1.8-33. For overview type 'help("mgcv-package")'.

##
## Attaching package: 'mgcv'
```

```
## The following object is masked from 'package:nnet':
##
##      multinom
```

Comparemos las predicciones con los distintos modelos:

- Cuando comparemos en la siguiente figura como varía la métrica de RMSE versus k, vemos que el valor más bajo del mismo se obtuvo para un k=50.

Figura 6: Comparación de RMSE para los modelos en función del valor de k

Ahora podemos visualizar las estimaciones en un scatter para ver cuanto se alejan de la relación 1:1 entre los valores estimados y predichos. De esta gráfico se observa que ningún modelo parece estimar correctamente el score de las películas, dado que vemos que para distintos valores del score observado se obtiene una predicción que se encuentra entre 6 y 7 del score.

Comparación de modelos En esta sección vamos a implementar una diversidad de modelos y comparar su performance.

- Dividir al conjunto de datos en entrenamiento y testeo (tambien puede usar otra técnica, como validación cruzada). Con todas las variables que tiene disponibles, probar al menos 10 modelos diferentes y elegir el que minimice el error cuadrático medio de predicción para el rating de IMDB.

Primero vamos a generar un nuevo dataframe con todos los features que podemos utilizar.

Ahora vamos a seleccionar 10 modelos distintos y compararlos para quedarnos con el que tenga el menor RMSE. Para este punto también vamos a utilizar la librería caret que nos va a permitir tunear los modelos, hacer selección de variables de una forma más simple. Los modelos que vamos a evaluar serán distintas variaciones de los modelos introducidos en las secciones anteriores.

- Modelos lineales mixtos

Modelos GAM diferentes valores de k

Figura 7: Comparación entre los valores observados y estimados de cada modelo

```

c) Modelos aditivos utilizando la libreria caret

Para el siguiente modelo, se eliminaron del dataset algunas variables dado por el tiempo que tardaba el modelo en realizar el ajuste de los parámetros (estas variables fueron: nombre, año y país).

```
## Loading required package: lattice

##
## Attaching package: 'caret'

## The following object is masked from 'package:purrr':
##
##      lift

## Generalized Additive Model using Splines
##
## 29229 samples
## 20 predictor
##
## No pre-processing
```

```
## Resampling: Bootstrapped (25 reps)
## Summary of sample sizes: 29229, 29229, 29229, 29229, 29229, 29229, ...
## Resampling results across tuning parameters:
##
##   select  RMSE      Rsquared  MAE
##   FALSE   0.9074124  0.2818155  0.6847809
##   TRUE    0.9074260  0.2817961  0.6848217
##
## Tuning parameter 'method' was held constant at a value of GCV.Cp
## RMSE was used to select the optimal model using the smallest value.
## The final values used for the model were select = FALSE and method = GCV.Cp.
```

Figura 8: RMSE selección de variables

d) Modelo GLM bayesiano utilizando la libreria caret

```
## Bayesian Generalized Linear Model
##
## 29229 samples
## 20 predictor
##
## No pre-processing
## Resampling: Bootstrapped (25 reps)
## Summary of sample sizes: 29229, 29229, 29229, 29229, 29229, 29229, ...
## Resampling results:
##
##   RMSE      Rsquared  MAE
##   0.9158804  0.2683681  0.6950728
```

e) Modelos lineales mixtos en carte utilizando selección de variables

```
## Start: AIC=82537.77
```

```
